A coded character set (CCS) is a function that maps characters to code points (each code point represents one character). For example, in a given repertoire, the capital letter "A" in the Latin alphabet might be represented by the code point 65, the character "B" to 66, and so on.

important when you use database functions to compare, convert and measure the data. For example, the LENGTH of a field may depend on its character set, as do string comparisons using LIKE and =. The method used to compare strings is called a collation. Character sets and collations in MySQL are an in-depth subject.

ASCII was incorporated into the Unicode (1991) character set as the first 128 symbols, so the 7-bit ASCII characters have the same numeric codes in both sets. This allows UTF-8 to be backward compatible with 7-bit ASCII, as a UTF-8 file containing only ASCII characters is identical to an ASCII file containing the same

History And **HTML Character Codes & Symbols**

Unicode is a character set. UTF-8 is encoding. Unicode is a list of characters with unique decimal numbers (code points). A = 65, B = 66, C = 67, This list of decimal numbers represent the string "hello": 104 101 108 108 111. Encoding is how these numbers are translated into binary numbers to be stored in a computer:
